# **9.1. Historical Background of CNN**

- Feed-forward Neural Networks (Chap. 5)
	- Fully-Connected
	- Too many weights for training
	- Slow learning convergence and High computational complexity
	- Overspecialization to training samples (poor generalization performance)
	- ➢ Locally-Connected Networks (Visual pathway of mammal)
- Visual Pathway
	- Hubel and Wiesel (1950s and 1960s)
		- Cat and monkey visual [cortexes](https://en.wikipedia.org/wiki/Cortex_(anatomy)) contain neurons that individually respond to small regions of the [visual field](https://en.wikipedia.org/wiki/Visual_field).  $\rightarrow$  Receptive Field
		- Simple Cells in V1 layer, whose output is maximized by straight edges having particular orientations within their receptive field
		- Complex Cells in V1 and V2 layer, which have larger [receptive fields](https://en.wikipedia.org/wiki/Receptive_field), whose output is insensitive to the exact position of the edges in the field.
- Visual Pathway
	- Keiji Tanaka (1990s)
		- Monkey visual **[cortexes](https://en.wikipedia.org/wiki/Cortex_(anatomy))**
		- Input End: Visual cells respond to simple features
		- Output End: Visual cells respond to complex features

LTI(Linear Time Invariant) System

 $y[n] = T(ax_1[n] + bx_2[n]) = aT(x_1[n]) + bT(x_2[n]) = ay_1[n] + by_2[n]$ 

#### LTI(Linear Time Invariant) System

#### Convolution

$$
y[n] = \sum_{k=-\infty}^{\infty} x[k]h[n-k] = x[n] \times h[n]
$$

The Communitive Law

$$
x[n] \times h[n] = h[n] \times x[n]
$$

 $\bigcirc$  입력  $x[k]$ 에 디지털 필터  $h[k]$ 를 좌우대칭으로 변형하여  $h[-k]$ 를 만든 후, 2 n만큼 이동한  $h[-(k-n)] = h[n-k]$ 를 곱하고, 3 그 결과들을 모든  $k$ 에 대하여 더한 결과를 출력 함수  $y[n]$ 으로 내어 놓는다. 즉, 입력  $x[k]$ 에 필터함수  $h[k]$ 를 역방향으로 씌워서 필터 출력을 얻어내며, 4 이를 모든  $n$ 에 대하여 이동하면서 출력 함수  $y[n]$ 을 구한다.

$$
y[n] = \sum_{k=-\infty}^{\infty} h[k]x[n-k] = h[n] \times x[n]
$$

# **9.3. Convolutional Neural Network(CNN)**

- CNN
	- consists of Convolution layer, Pooling Layer, and Fully-Connected Layer

- Convolution Layer
	- 2-D convolution

 $h_j[\mu,\nu] = \mathbf{w}_j \times \mathbf{x} = \sum_{i=-\frac{(z-1)}{(z-1)/2}}^{\frac{(z-1)}{2}} \sum_{k=-\frac{(z-1)}{(z-1)/2}}^{\frac{(z-1)}{2}} w_j[i,k] x[\mu+i,\nu+k]$ 

- Feature Map (3-D)
- Padding
- Stride
- Local Connectivity (receptive field of neuron)
- Parameter Sharing (filter or kernel)

- Pooling Layer
	- A form of nonlinear down sampling
		- The exact location of a feature is less important than its rough location relative to other features. The pooling layer serves to progressively reduce the spatial size of the representation, to reduce the number of parameters, and amount of computation in the network, and hence to also control [overfitting.](https://en.wikipedia.org/wiki/Overfitting) It is common to periodically insert a pooling layer between successive convolutional layers in a CNN architecture. The pooling operation provides another form of translation invariance.
	- Max pooling is the most common
		- It [partitions](https://en.wikipedia.org/wiki/Partition_of_a_set) the input image into a set of non-overlapping rectangles and, for each such sub-region, outputs the maximum.
	- Average Pooling, L2-norm Pooling

- ReLU Layer
	- ReLU(Rectified Linear Unit) for feature maps (before pooling)

 $f(x) = max(0,x)$ 

• Other functions are also used to increase nonlinearity

 $f(x) = \tanh(x)$  $f(x) = (1 + e^{-x})^{-1}$ 

- Fully Connected Layer
	- After several convolutional and max pooling layers, the high-level reasoning in the neural network is done via fully connected layers. Neurons in a fully connected layer have connections to all activations in the previous layer, as seen in regular [\(non-convolutional\)](https://en.wikipedia.org/wiki/Artificial_neural_network) artificial neural networks.
	- SoftMax Output Node

$$
y_k = \frac{e^{\hat{y_k}}}{\sum_j \overline{e^{\hat{y_j}}}}
$$

• CE(Cross-Entropy) Loss Function

$$
E_{CE} = -\sum_{k} t_k \log{(y_k)}
$$

#### 예제 9.3-1

아래 그림으로 2차원 공간 상에 6×6 크기의 입력과 3×3 크기의 수직성분 추출 필터가 주어졌다. 패딩은 영의 값을 사용하여, 이동 폭은 1로 한 경우 컨볼루션 층의 결과를 구하라. 그 다음에 ReLU 함수를 거친 후 2×2 맥스풀링을 한 결과를 단계적으로 보여라. 여기서, 입력의 픽셀 값과 필터 값은 0(밝은 부분)과 1(어두운 부분)으로 정하였다.

풀이

 $6\times 6$  크기의 입력에 패딩을 적용 후  $3\times 3$  크기의 필터를 적용한 컨볼루션 층 출력은  $6\times 6$ 으로

와 같이 된다. 컨볼루션 결과에 음의 값이 없으므로 ReLU층을 거쳐도 동일한 결과를 얻게 된다. 여기에 2×2 맥스풀링을 거치면 그 결과는

이 된다.

# **9.4. Hyperparameters and Regularization**

### • **Choosing Hyperparameters**

CNNs use more [hyperparameters](https://en.wikipedia.org/wiki/Hyperparameter_(machine_learning)) than a standard multilayer perceptron (MLP). While the usual rules for [learning rates](https://en.wikipedia.org/w/index.php?title=Learning_rate&action=edit&redlink=1) and [regularization](https://en.wikipedia.org/wiki/Regularization_(mathematics)) constants still apply, the following should be kept in mind when optimizing.

#### • **Number of filters**

✓Since feature map size decreases with depth, layers near the input layer will tend to have fewer filters while higher layers can have more. To equalize computation at each layer, the product of feature values  $v_a$  with pixel position is kept roughly constant across layers. Preserving more information about the input would require keeping the total number of activations (number of feature maps times number of pixel positions) non-decreasing from one layer to the next.

#### • **Filter shape**

✓Common filter shapes found in the literature vary greatly, and are usually chosen based on the dataset. The challenge is, thus, to find the right level of granularity so as to create abstractions at the proper scale, given a particular dataset, and without [overfitting.](https://en.wikipedia.org/wiki/Overfitting)

#### • **Max pooling shape**

✓Typical values are 2×2. Very large input volumes may warrant 4×4 pooling in the lower layers. However, choosing larger shapes will dramatically reduce the [dimension](https://en.wikipedia.org/wiki/Dimensionality_reduction) of the signal, and may result in excess [information](https://en.wikipedia.org/wiki/Data_loss) loss. Often, non-overlapping pooling windows perform best.

### • **Regularization Methods**

#### • **Dropout**

 $\checkmark$  Because a fully connected layer occupies most of the parameters, it is prone to <u>overfitting</u>.

✓ One method to reduce overfitting is [dropout.](https://en.wikipedia.org/wiki/Dropout_(neural_networks)) At each training stage, individual nodes are either "dropped out" of the net with probability  $T-p$  so that a reduced network is left; incoming and outgoing edges to a dropped-out node are also removed. Only the reduced network is trained on the data in that stage. The removed nodes are then reinserted into the network with their original weights.

#### • **Stochastic pooling**

 $\checkmark$  In stochastic pooling, <sup>[\[52\]](https://en.wikipedia.org/wiki/Convolutional_neural_network#cite_note-55)</sup> the conventional <u>[deterministic](https://en.wikipedia.org/wiki/Deterministic_algorithm)</u> pooling operations are replaced with a stochastic procedure, where the activation within each pooling region is picked randomly according to a [multinomial](https://en.wikipedia.org/wiki/Multinomial_distribution) distribution, given by the activities within the pooling region. This approach is free of hyperparameters and can be combined with other regularization approaches, such as dropout and data augmentation.

#### • **Number of parameters**

 $\checkmark$  Another simple way to prevent overfitting is to limit the number of parameters, typically by limiting the number of hidden units in each layer or limiting network depth. For convolutional networks, the filter size also affects the number of parameters. Limiting the number of parameters restricts the predictive power of the network directly, reducing the complexity of the function that it can perform on the data, and thus limits the amount of overfitting.

#### • **Weight decay**

 $\checkmark$  A simple form of added regularizer is weight decay, which simply adds an additional error, proportional to the sum of weights (L1 [norm](https://en.wikipedia.org/wiki/L1-norm)) or squared magnitude (L2 [norm\)](https://en.wikipedia.org/wiki/L2_norm) of the weight vector, to the error at each node. The level of acceptable model complexity can be reduced by increasing the proportionality constant, thus increasing the penalty for large weight vectors.

$$
(9.4.12)

낙오에 의한 오차함수의 기울기는 앙상블에 의한 오차함수의 기울기와 방향 동일 식(9.4.12)는 앙상블 오차함수가 조정된(regularized) 형태

$$
E_R = E_{ENS} + \frac{1}{2} \sum_{1=1}^{n} w_i^2 I_i^2 Var[\delta_i]
$$
 (9.4.13)

식 (9.4.13)의 마지막 황: 오차함수의 조정 황(regularization term)  
- 가중치의 크기를 제한: 과도한 학合 방지  
- 입력 콴기의 제곱과 낙오 변수의 분산에 의해 조정 하의 콴기 철정  
- 
$$
p_i = 0.5
$$
:  $Var[\delta_i]$ 가 최대가 되어 낙오에 의한 조정하여 흘고가 가장 콹  
- 1-  $p_i$  > 0.5: 조정의 흐과가 �}\nI지 앓으로서 연ж을 말이 끊게 톰  
- 시함 썰를 입력:  $E\left[\sum_{i=1}^{n} \delta_i w_i I_i\right] = \sum_{i=1}^{n} p_i w_i I_i$ , 전방향 계산 시  $w_i \leftarrow p_i \equiv$  골함

- 각 계층에서 모든 노드를 대상으로 평균과 분산을 구하여 정규화를 하는 것이 계층 정규화

- 평균과 표준편차: l 층의 가중치 합을 대상

$$
\mu^{(l)} = \frac{1}{H} \sum_{i=1}^{H} a_i^{(l)} \tag{9.4.18}
$$

$$
\sigma^{(l)} = \sqrt{\frac{1}{H} \sum_{i=1}^{H} (a_i^{(l)} - \mu^{(l)})^2}
$$
(9.4.19)

여기서, H는 l 층의 은닉노드 수

- 계층 정규화에서  $l$  층의 모든 노드는 같은 평균  $\mu^{(l)}$ 과 표준편차  $\sigma^{(l)}$ 를 사용하 여 정규화가 이루어짐

- 계층 정규화는 미니배치 크기에 영향을 받지 않아 온라인 학습에 적용가능

# **9.5. Different Type of Convolutions**

## • **Dilated Convolutions**

• Dilated convolutions introduce another parameter to convolutional layers called the **dilation rate**. This defines a spacing between the values in a kernel. A 3x3 kernel with a dilation rate of 2 will have the same field of view as a 5x5 kernel, while only using 9 parameters. Imagine taking a 5x5 kernel and deleting every second column and row.

### • **Transposed Convolutions**

- An actual deconvolution reverts the process of a convolution.
- A transposed convolution is somewhat similar because it produces the same spatial resolution a hypothetical deconvolutional layer would. However, the actual mathematical operation that's being performed on the values is different. A transposed convolutional layer carries out a regular convolution but reverts its spatial transformation.
- To achieve this, we need to perform some fancy padding on the input.
